(54) Title: INCREASING HYDROGEN ADSORPTION OF NANOSTRUCTURES STORAGE MATERIALS BY MODIFYING SP² COVALENT BONDS

(57) Abstract: According to the invention, nanostructured storage materials are provided for storing hydrogen. The nanostructured storage materials can include a network of light elements, such as Be, B, C, N, O, F, Mg, P, S, and Cl, coupled with sp² bonds. The hydrogen absorption to the nanostructured storage material is improved by modifying the sp² bonds. The sp² bonds can be modified by forming the nanostructured storage material from the above light elements, possibly with a shape other than a planar layer, and by introducing defects. A chemical vapor deposition technique can be used for the synthesis, where doping gases are included into the flow. Methods for forming the nanostructured storage material with defects include removing lights elements from the nanostructured storage material by irradiation with electrons, neutrons, ions, gamma rays, X-rays and microwaves.

INCREASING HYDROGEN ADSORPTION OF NANOSTRUCTURED STORAGE MATERIALS BY MODIFYING sp^2 COVALENT BONDS

BACKGROUND

5 FIELD OF INVENTION

The invention relates to hydrogen storage systems, more particularly to improving the adsorption of hydrogen in storage systems containing nanostructures.

DESCRIPTION OF RELATED ART

Hydrogen storage is the key unsolved problem of producing fuel cells for hydrogen-
10 powered automobiles or portable energy devices. In particular, storing hydrogen in large quantities safely and in a light container proved prohibitively difficult so far.

Several different techniques have been developed to tackle this problem. In some approaches hydrogen is stored in tanks under high pressure, for example, 300 atm. In other techniques hydrogen is liquefied at temperatures below 20 K with a helium-based cooling
15 system. Both of these techniques pose problems for practical use in automobiles. For example, all of the hydrogen is available for catastrophic release in an accident, raising the risk of explosion or fire. Furthermore, in order to store enough hydrogen to match the range of present day automobiles, the container has to have a volume of at least 50 gallons. Also, both in the high-pressure technique and in the helium-cooled technique the required
20 containers are heavy, and therefore inefficient for storage. Finally, both techniques consume a lot of energy for generating the high pressure or for liquefying the hydrogen.

Some other techniques adsorb hydrogen into solid materials. Several types of materials have been studied in this respect, including metal hydrides and glass microspheres. However, all the materials investigated so far have low hydrogen storage capacity, making
25 them non-competitive with gasoline.

Hydrogen can also be stored in carbon nanostructures, such as graphite or carbon nanofibers, according to the papers of A. Dillon et al. in *Nature*, vol. 386, p. 377 (1997), A. Chambers et al. in *J. Phys. Chem. B* vol. 102, p. 3378 (1998), and E. Poirier et al. in *Int. J. of Hydrogen Energy*, vol. 26, p. 831 (2001), and according to U.S. patent 5,663,951:

- 5 "Storage of hydrogen in layered nanostructures," by N. Rodriguez and R. Baker, and U.S. patent No. 4,960,450: "Selection and preparation of activated carbon for 25 fuel gas storage," by J. Schwarz et al.

Nanostructures can be defined as atomic structures that have a spatial extent of less than a few hundred nanometers in one, two, or all three dimensions. A class of nanostructures is
10 formed by planar networks, sometimes referred to as layered compounds. Layered compounds are often formed by elements coupled with sp^2 bonds. The origin of the sp^2 bonds will be presented on the example of elements of the second row of the periodic table, including boron, carbon, and nitrogen.

FIG. 1 shows an example of a second row element 4 coupled with sp^2 bonds, or orbitals, 8
15 to three other elements 12. The s orbital of the second row elements is filled with two electrons, and the p orbitals are partially filled. For example, boron has one electron, carbon has two, and nitrogen has three electrons in the p orbitals. When the second row elements form chemical bonds, one of the s electrons is promoted into an empty p orbital - for example into the p_z orbital in carbon, leaving only one s electron. This one s electron and
20 two of the p electrons hybridize into three sp^2 hybrid orbitals. The remaining p electrons - none in boron, one in carbon, and two in nitrogen - occupy a p orbit that does not participate in the bonding. The three hybridized electrons repel each other, and hence form three sp^2 orbitals 8 as far as possible away from each other. An optimal configuration is when the three sp^2 orbitals 8 make 120 degrees with each other, defining a plane. Connecting several
25 second row elements with planar sp^2 orbitals 8 spans the defined plane, thus forming the aforementioned planar networks. Possible planar networks of the sp^2 bonded materials include triangular lattices.

Typically hydrogen adsorbs to nanostructures with physical interactions, an example of which is the van der Waals interaction. Such an adsorption is referred to as physisorption,

in contrast to chemisorption, where the adsorbate forms a chemical bond with the surface. A detailed comparison between physisorption and chemisorption is provided in co-pending U.S. Patent application, entitled: "Hydrogen Storage in Nanostructures with Physisorption," by Keith Bradley, Philip G. Collins, Jean-Christophe P. Gabriel, Young-Kyun Kwon,

5 Seung-Hoon Jhi, and George Grüner.

FIG. 2A illustrates the bonding of a hydrogen molecule 16 to a triangular sp^2 bonded layer 20 of carbon atoms, wherein the triangular layer is sometimes referred to as a graphene sheet.

FIG. 2B illustrates the energy of hydrogen molecule 16, expressed in electron Volts, as a
10 function of distance from triangular sp^2 bonded layer 20, expressed in Nanometers. Hydrogen molecule 16 will typically be located at a distance from the graphene sheet where the energy is lowest. In the example of FIG. 2B this distance is about 0.27 nanometers. The minimum value of the energy is often referred to as a binding energy, E_B , which in this example takes the value of $E_B(\text{planar}) = 0.10 \text{ eV}$.

15 Storing hydrogen in sp^2 bonded nanostructures has the following advantages. Hydrogen, adsorbed to the nanostructures, desorbs slowly and thus it is not available for catastrophic release, for example, in an automobile accident. Furthermore, because of their large surface area, nanostructures are capable of bonding very large quantities of hydrogen, giving rise to a much higher weight % storage efficiency than the aforementioned high pressure and
20 cooling techniques.

However, the referenced works have the following disadvantages. Typically they consider hydrogen storage at ambient temperatures, where the storage capacity falls far short of the theoretical value, making those works economically non-viable. Also, the works that consider storage at other temperatures reported insufficient storage efficiencies.

25 FIG. 3 shows the amount of hydrogen, adsorbed on triangular sp^2 bonded layer 20, as a function of temperature, expressed as a percentage of the amount of hydrogen adsorbed at zero temperature. As shown in FIG. 3, hydrogen desorbs from triangular sp^2 bonded layer

20 at a relatively well defined the desorption temperature, T_D . At about 120-140% of T_D practically all hydrogen is desorbed.

The desorption temperature, T_D , depends on the pressure, as illustrated in FIG. 3. For example, raising the pressure from about 1 atm to about 10 atm, and then from about 10 atm
5 to about 100 atm increases the desorption temperature about 20% each time. In FIG. 3 the temperature T is shown relative to the desorption temperature T_D at 1atm pressure, $T_D(1\text{atm})$. $T_D(1\text{atm})$ is about 60K for graphene sheets.

The desorption temperature of hydrogen in relation to many nanostructures is well below the ambient temperature of about 300K. Since large amounts of hydrogen can be stored
10 only at temperatures around or below T_D , many adsorption based hydrogen storage systems have to be cooled to provide a competitive storage system.

The desorption temperature T_D , determines the type of cooling necessary for the efficient operation of the storage system. Many cooling systems utilize liquid nitrogen or liquid helium as a coolant.

15 Cooling systems utilizing liquid nitrogen have several advantages over systems utilizing liquid helium. Liquid nitrogen is much cheaper per liter than liquid helium. Nitrogen becomes a liquid at 77 K, whereas helium becomes a liquid at 4.2 K. It requires much less energy to cool a system to a temperature of 77 K, than to a temperature of 4.2 K. It also requires a much simpler and therefore lighter cooling apparatus to maintain a temperature of
20 about 77 K, than to maintain a temperature of about 4.2 K.

Therefore there is a need for hydrogen storage systems that contain sp^2 bonded nanostructures, wherein the composition and structure of the nanostructure is selected to ensure high storage efficiency, and wherein the hydrogen adsorbs to the nanostructure with a binding energy large enough to permit operating the hydrogen storage system at
25 technologically advantageous temperatures.

SUMMARY

According to the invention, a nanostructured storage material is provided, capable of storing hydrogen. The nanostructured storage material includes a network of light elements, wherein the light elements are selected from Be, B, C, N, O, F, Mg, P, S, and Cl. Light
5 elements are utilized to improve the weight % storage efficiency of storage systems, and thus making them more competitive.

Theoretical considerations and experiments have shown that some networks, containing modified sp^2 bonds, are capable of adsorbing more hydrogen than planar triangular lattices that are formed from one type of atoms, which are coupled by sp^2 bonds. In embodiments
10 of the invention the hydrogen adsorption to nanostructured storage material is improved by suitably modifying the sp^2 bonds of a network to increase the binding energy of hydrogen.

The sp^2 bonds of the nanostructured storage material can be modified by several methods. These methods include forming the nanostructured storage material from the above selected light elements; forming the nanostructured storage material with a shape other than a planar
15 layer; and introducing defects into the nanostructured storage material.

Hydrogen has a higher binding energy to the nanostructured storage materials with modified sp^2 bonds that correspond to embodiments of the invention. A higher binding energy causes a higher desorption temperature for hydrogen, making the nanostructured storage materials, corresponding to embodiments of the invention, economically
20 competitive for storing hydrogen in transportation and other applications.

Methods for forming the nanostructured storage material with a chemical composition that modifies the sp^2 bonds include using a chemical vapor deposition technique, where doping gases are included into the flow of the chemical vapor deposition synthesis. Other methods include hot-pressing light elements with graphite powder to form electrodes, and
25 then using the electrode for performing an arc synthesis of the nanostructured storage material.

Methods for forming the nanostructured storage material with defects include removing light elements from the nanostructured storage material by irradiation with electrons, neutrons, ions, gamma rays, X-rays, and microwaves. The same irradiation techniques can be used to generate 5-7 defects as well.

5

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates an element forming sp^2 bonds.

FIG. 2A illustrates a hydrogen molecule adsorbed to a triangular lattice.

FIG. 2B illustrates the dependence of the energy of the hydrogen molecule on the distance
5 between the hydrogen molecule and the triangular lattice.

FIG. 3 illustrates the temperature dependence of the storage capacity of nanostructures as a function of temperature at different pressures.

FIG. 4A illustrates a hydrogen molecule adsorbed to a triangular lattice of binary composition.

10 FIG. 4B illustrates the dependence of the energy of the hydrogen molecule on the distance between the hydrogen molecule and the triangular lattice of binary composition.

FIG. 4C illustrates a hydrogen molecule adsorbed to a modified triangular lattice of binary composition.

FIG. 4D illustrates the dependence of the energy of the hydrogen molecule on the distance
15 between the hydrogen molecule and the modified triangular lattice of binary composition.

FIG. 5A illustrates a hydrogen molecule adsorbed to a nanocage.

FIG. 5B illustrates the dependence of the energy of the hydrogen molecule on the distance between the hydrogen molecule and the nanocage.

FIG. 6 illustrates a hydrogen molecule adsorbed to a BN nanocage.

20 FIG. 7A illustrates a hydrogen molecule adsorbed to a nanotube.

FIG. 7B illustrates the dependence of the energy of the hydrogen molecule on the distance between the hydrogen molecule and the nanotube.

FIG. 8A illustrates a hydrogen molecule adsorbed to a carbon layer with an impurity.

FIG. 8B illustrates the dependence of the energy of the hydrogen molecule on the distance between the hydrogen molecule and the carbon layer with an impurity.

FIG. 8C illustrates the dependence of the energy of the hydrogen molecule on the distance
5 between the hydrogen molecule and the BN layer with an impurity.

FIG. 9A illustrates a hydrogen molecule adsorbed to a layer with a 6 atom vacancy.

FIG. 9B illustrates the dependence of the energy of the hydrogen molecule on the distance between the hydrogen molecule and the carbon layer with a hexagonal defect.

FIG. 10A illustrates a hydrogen molecule adsorbed to a layer with a 5-7 defect.

10 FIG. 10B illustrates the dependence of the energy of the hydrogen molecule on the distance between the hydrogen molecule and the layer with a 5-7 defect.

FIG. 11A illustrates a hydrogen molecule adsorbed to a charged layer.

FIG. 11B illustrates the dependence of the energy of the hydrogen molecule on the distance between the hydrogen molecule and the charged layer.

15

DETAILED DESCRIPTION

In accordance with the invention, a nanostructured storage material 22 is presented for storing hydrogen. Nanostructured storage material 22 includes a network of light elements 24, selected from Be, B, C, N, O, F, Mg, P, S, and Cl. Light elements 24 are utilized to
20 improve the weight % storage efficiency of nanostructured storage material 22, thus making it suitable for use in transportation and other industrial applications.

Previous works have described planar triangular lattices, formed from one type of atoms, coupled by sp^2 bonds. In the present invention, the light elements of the network are coupled by modified sp^2 bonds. Theoretical considerations and experiments have shown

that some networks, containing modified sp^2 bonds, are capable of adsorbing more hydrogen than planar triangular lattices that are formed from one type of atoms, which are coupled by sp^2 bonds. Modifying the sp^2 bonds can change the hybridization of the s and p electrons. Changing the hybridization of the s and p electrons modifies the electronic states.

- 5 The binding of hydrogen molecules is sensitive to the character of the electronic states. Therefore, the binding energy of hydrogen can be controlled by modifying the sp^2 bonds. In particular, in embodiments of the invention the binding energy of hydrogen is increased by suitably modifying the sp^2 bonds. In these embodiments the hydrogen adsorption to nanostructured storage material 22 is also improved by modifying the sp^2 bonds of the
- 10 network. The improvement of hydrogen adsorption causes, for example, the increase of the desorption temperature T_D , and the increase of the hydrogen storage capacity near T_D .

- The sp^2 bonds of nanostructured storage material 22 can be modified by several methods. These methods include forming nanostructured storage material 22 from the above selected light elements 24; forming nanostructured storage material 22 with a shape other than a
- 15 planar layer; and introducing defects into nanostructured storage material 22.

- FIG. 4A illustrates an embodiment where the adsorption of hydrogen molecule 16 to nanostructured storage material 22 is enhanced relative to the adsorption to a carbon layer by modifying the sp^2 bonds via forming nanostructured storage material 22 with a binary composition of two light elements 24-1 and 24-2. For example, the binary composition can
- 20 be boron nitride, BN. In FIG. 4A boron atoms 24-1 are indicated by large circles and nitrogen atoms 24-2 by small circles.

- FIG. 4B illustrates the energy of hydrogen molecule 16 as a function of distance from the plane of nanostructured storage material 22. The binding energy is approximately $E_B(\text{BN, planar})_{\text{boron}} = 0.13 \text{ eV}$, when hydrogen molecule 16 adsorbs to boron atoms 24-1, a
- 25 value about 30% higher than $E_B(\text{C, planar}) = 0.10 \text{ eV}$ for pure carbon layers.

The binding energy E_B determines the desorption temperature T_D . For example, the graphene sheet binding energy $E_B(\text{C, planar}) = 0.10 \text{ eV}$ approximately corresponds to a $T_D(\text{C, planar})$ of 60K at a pressure of 1 atm. As the binding energy of the planar BN layers,

$E_B(\text{BN,planar})$, is about 30 % higher than the binding energy of carbon layers, $E_B(\text{C,planar})$, the desorption temperature $T_D(\text{BN,planar})$ of BN layers is also enhanced from about 60K to about 80K in this embodiment.

FIG. 4C illustrates another embodiment where the adsorption of hydrogen molecule 16 to nanostructured storage material 22 is enhanced relative to the adsorption to a carbon layer by modifying the sp^2 bonds via forming nanostructured storage material 22 with a binary composition of two light elements 24-1 and 24-2 with the formula A_3B_4 . For example, the binary composition can be carbon nitride, C_3N_4 . In FIG. 4C carbon atoms 24-1 are indicated by large circles and nitrogen atoms 24-2 by small circles.

FIG. 4D illustrates the energy of hydrogen molecule 16 as a function of distance from the plane of nanostructured storage material 22. The binding energy is approximately $E_B(\text{CN,planar}) = 0.26 \text{ eV}$, a value about 160% higher than $E_B(\text{C,planar}) = 0.10 \text{ eV}$ for pure carbon layers.

Related embodiments include other nanostructured storage materials 22 with planar forms, for example, thin nanoplatelets, thick nanoplatelets, and intercalated nanoplatelets, with thicknesses from about 0.3 nm to about 100 nm, and lateral size from about 0.5 nm to about 500 nm.

All these nanostructured storage materials 22 can acquire higher bonding energies by having a binary chemical composition of the above light elements, instead of a monoatomic composition. In some embodiments binary compositions include BN, MgB_2 , Be_3N_2 , BeB_2 , B_2O , BeO , AlCl_3 , Al_4C_3 , AlF_3 , Al_2O_3 , Al_2S_3 , Mg_2Si , Mg_3N_2 , Li_3N , Li_2S , Na_2S , AlB_2 , and Na_2S_4 . In some embodiments nanostructured storage material 22 includes mixtures of binary compounds with these chemical compositions.

Also, chemical compositions having more than two elements can enhance the binding energy. Examples include nanostructured storage materials 22 with $\text{B}_x\text{C}_y\text{N}_z$ type composition, where x, y, and z are integers.

FIG. 5A illustrates some embodiments of the invention, where the adsorption of hydrogen molecule 16 to nanostructured storage material 22 is enhanced by deforming sp^2 bonds 8. One way to deform sp^2 bonds 8 is to introduce a curvature into nanostructured storage material 22. FIG. 5A illustrates a nanocage 32, which consists of twenty light elements 24, for example, carbon. Nanocage 32 consists of only 12 pentagons without hexagon ring. Due to the large curvature of the layer of nanostructured storage material 22, the sp^2 bonding characteristics are significantly modified. Large families of nanocages are known in the art, including nanocages of about 20 to about 100 atoms, as well as empty nanocages, filled nanocages, and multifaceted nanocages. There are also families of nanocages with non-spherical structures. For example, nanocages elongated along an axis are referred to as nanococoons, examples of which include empty nanococoons, filled nanococoons, and multifaceted nanococoons. Nanocages with more extensively deformed shapes include, for example, nanotorii, nanocoils, and nanohorns. Also, the chemical composition of nanocages can be heteroatomic, i.e., they can contain more than one type of atoms. Finally, nanocages can have heterogeneous forms, where a part of the nanocage has one of the above-defined forms and another part of the nanocage has another of the above-defined forms. All varieties of nanocages are understood to be within the scope of the invention.

FIG. 5B illustrates the dependence of energy on the distance between the surface of nanocage 32 and hydrogen molecule 16. The binding energy $E_B(C, cage)$ is about 0.11 eV, about 10 % bigger than $E_B(C, planar)$, corresponding to an enhanced value of T_D of about 65K in this embodiment.

Forming nanocage 32 with a heteroatomic composition, for example, the binary composition of BN, can further enhance the binding energy E_B and desorption temperature T_D . Some embodiments are formed from other combinations of light elements 24.

FIG. 6 illustrates some embodiment that is a combination of the embodiments of FIG. 4A and 5A. FIG. 6 shows a nanocage 32, with 60 atoms in it. Some embodiments are formed from a single light element 24, others are formed from two different light elements 24-1 and 24-2, such as boron and nitrogen atoms. The chemical notation for this nanocage is $B_{30}N_{30}$.

Nanocages containing 60, or close to 60 atoms, are often referred to as "buckyballs."

Unlike the usual hexagonal boron-nitride layer, where only boron-nitrogen (BN) pair bonds exist, nanocage 32 contains boron-boron (BB) and nitrogen-nitrogen (NN) pair bonds as well as BN pair bonds, because of 12 pentagons in its structure. Therefore, nanocage 32
5 exhibits unique electronic properties compared to sp^2 -bonded boron-nitride systems, which do not have BB or NN pair bonds. The binding energy $E_B(\text{buckyball})$ and $T_D(\text{buckyball})$ is also enhanced relative to $E_B(\text{C,planar})$.

FIG. 7A illustrates some embodiments where the adsorption of hydrogen molecule 16 to nanostructured storage material 22 is enhanced by deforming sp^2 bonds 8 in a tubular
10 manner. Here nanostructured storage material 22 is deformed into a nanotube 36, formed from two different light elements 24-1 and 24-2, for example, boron and nitrogen. Nanotubes have many advantageous properties, including mechanical and electric conducting advantages. Related embodiments utilize other types of nanotube-related nanostructured storage materials 22. A non-exhaustive list of nanotube-related
15 nanostructured storage materials 22 include:

- nanotubes of the following kinds: single walled, double walled, multi walled, with zig-zag chirality, or a mixture of chiralities, twisted, straight, bent, kinked, curled, flattened, and round;
- nanofibers of the following kinds: turbostratic, highly oriented, twisted, straight, curled
20 and rigid;
- nanorods, and nanowires;
- ropes of nanotubes, twisted nanotubes, and braided nanotubes;
- small bundles of nanotubes (with a number of tubes less than ten), medium bundles of nanotubes (with a number of tubes in the hundreds), and large bundles of nanotubes (with a
25 number of tubes in the thousands).

FIG. 7B illustrates the dependence of energy on the distance between the surface of nanotube 36 and hydrogen molecule 16. In embodiments with a monoatomic composition, such as carbon, the binding energy $E_B(\text{C, nanotube})$ is only marginally bigger than $E_B(\text{C, planar})$. In embodiments, where nanotube 36 is formed with a heteroatomic composition, for example, with the binary composition BN, the binding energy E_B and desorption temperature T_D can be bigger.

In some embodiments the adsorption of hydrogen molecule 16 to nanostructured storage material 22 is enhanced by modifying sp^2 bonds locally via the introduction of localized defects. The localized defects can modify the hybridization of the s and p electrons locally.

10 The modification of the hybridization of the s and p electrons can change the electronic states. The binding of hydrogen molecules is very sensitive to the character of the electronic states. Therefore the binding energy can be controlled by modifying the sp^2 bonds by introducing defects into nanostructured storage material 22.

FIG. 8A illustrates some embodiments, where the localized defect is formed by replacing one of the light elements 24 of a layer with a defect atom 42 in nanostructured storage material 22. In the displayed example a boron atom 42 has been included in a layer of carbon atoms 24. Hydrogen molecule 16 has an enhanced binding energy at the location of defect atom 42.

FIG. 8B illustrates the dependence of energy on the distance between the surface of nanostructured storage material 22 and hydrogen molecule 16 near the location of defect atom 42. In the case of the example, the binding energy $E_B(\text{C, boron defect})$ is about 0.14 eV, about 40 % bigger than $E_B(\text{C, planar})$, corresponding to an enhanced value of T_D of about 85K in this embodiment.

Some embodiments include defects formed with atoms other than boron. Some other embodiments include other type of defects, for example, multiatomic defects, where the atoms can be of the same element or different ones, and can be located next to each other or at a few lattice spacing away. All these defect varieties can further enhance the binding energy E_B and desorption temperature T_D .

FIG. 8C illustrates some embodiment, where nanostructured storage material 22 has a binary chemical composition of light elements 24, for example, boron nitride, BN, and a carbon atom is inserted as defect atom 42. FIG. 8C illustrates the dependence of energy on the distance between the surface of nanostructured storage material 22 and hydrogen molecule 16 near the location of defect atom 42. The binding energy E_B (BN, carbon impurity) is about 0.20 eV, about 100 % bigger than E_B (C,planar), corresponding to an enhanced value of T_D of about 120K in this embodiment.

Defect atoms, or impurities, can be implanted into nanostructured storage materials 22 by several different methods. In some embodiments doping gases are added into the flow of a chemical vapor deposition synthesis. Doping gases include NH_3 , CH_3NH_2 , $(CH_3)_2NH$, $(CH_3)_3N$, BCl_3 , BF_3 , B_2H_6 (or any other borohydride), SiH_4 , Si_2H_6 , $SiCl_4$, SiF_4 , SiH_2Cl_2 , H_2S , and PH_3 .

Some embodiments introduce traces of the element, intended to serve as defect atoms, into a graphite powder. The resulting graphite powder is subsequently hot pressed into the shape of a rod that can be used as an electrode in a classical arc synthesis of nanostructured storage material 22. Most elements of the periodic table can serve as impurities.

Some embodiments introduce the impurities by solid-state chemistry methods, for example, by ball milling nanostructured storage material 22 with a powder of the element, intended to serve as an impurity. In some embodiments nanostructured storage material 22 are ball-milled under a high-pressure atmosphere, containing the element intended to serve as an impurity.

FIG. 9A illustrates some embodiments, where the localized defect is formed by removing one or more atoms of nanostructured storage material 22, for example, the atoms of a hexagon of the triangular lattice. In different embodiments different numbers of atoms can be removed. In some embodiments a different type of atoms can be inserted in the place of the removed atoms. FIG. 9A illustrates an example, where in a layer of carbon atoms 24 six carbon atoms of a hexagon 50 are removed and replaced with six hydrogen atoms 46 to saturate the unpaired dangling bonds of the triangular lattice.

The carbon atoms can be removed by, for example, exposing nanostructured storage material 22 to a flow of ozone, which breaks up some of the hexagons and inserts oxygen into the hexagons. Some hexagons can be completely eliminated by this process.

Afterwards, nanostructured storage material 22 can be annealed at a temperature in the
5 range of about 400°C to about 1800°C. The annealing can take place in vacuum, in a neutral atmosphere, or in an atmosphere containing H₂, for example, an Ar/H₂ mixture. In this atmosphere the oxygen forms CO and CO₂ with the carbon atoms of the nanostructured storage material 22. In some embodiments the carbon atoms are removed in groups, several of them belonging, for example, to the same hexagon. In some
10 embodiments carbon atoms are removed in big enough groups to cause indentations with a size of about 10 - 100 nanometers, detectable with transmission electron microscopy. The CO and CO₂ leave nanostructured storage material 22 and in some embodiments hydrogen can take the place of some of the carbon atoms.

More generally, removing one or more atoms can be achieved by solution chemistry by
15 partially attacking/etching the materials. For example, in the case of carbeneous materials, this can be achieved using strong oxidizing acidic media such as mixtures of H₂SO₄ and HNO₃, or H₂SO₄ and H₂O₂. As another example, in the case of BN, this can be done by partial reaction with F₂, HF, or nitric acid.

In some embodiments the carbon atoms are removed from the nanostructure by irradiation
20 with electrons, neutrons, ions, gamma rays, X-rays, and microwaves. Subsequent exposure to different gaseous atmospheres can again saturate the unsaturated bonds with, for example, hydrogen.

FIG. 9B illustrates the dependence of energy on the distance between the surface of nanostructured storage material 22 and hydrogen molecule 16 near the location of a 6 atom
25 vacancy. The binding energy $E_B(\text{C}, 6\text{-atom-vacancy})$ is about 0.14 eV, about 40 bigger than $E_B(\text{C}, \text{planar})$, corresponding to an enhanced value of T_D of about 85K in this embodiment.

FIG. 10A illustrates some embodiments, where the localized defect is a "5-7" defect. 5-7 defects are a typical defect of triangular lattices. The regular building block of triangular

lattices is a hexagon 50, which is a ring of six atoms. A triangular lattice can be formed by covering a plane with hexagons. As shown in FIG. 10A, a hexagon can be deformed into a pentagon defect 54 by eliminating one of the atoms from hexagon 50. Hexagon 50 can also be deformed into a heptagon defect 58 by adding an atom to hexagon 50. The formation of
5 pentagon defect 54 or heptagon defect 58 by itself requires considerable energy, because forming these defects distorts the surrounding lattice extensively. Therefore pentagon and hexagon defects 54, 58 exist in significant concentration only close to the melting temperature of the lattice.

To avoid the high energy of formation, pentagon and heptagon defects 54, 58 often form
10 pairs, known as 5-7 defects, as shown by the pair 54 - 58 in FIG. 10A. 5-7 pairs cause much less distortion of the surrounding lattice and thus cost less energy to form. However, even the formation of 5-7 defects has a considerable energy cost, so at lower temperatures a 5-7 pair defect will typically pair up with an other 5-7 pair defect, oriented in the opposite direction. In the example of FIG. 10A the second 5-7 pair defect is formed from pentagon
15 62 and heptagon 66, and has an orientation opposite of the 54 - 58 pair defect. This 5-7-7-5 configuration can also be generated by rotating a bond of a hexagon ring by 90° in a triangular lattice, sometimes referred to as a Stone-Wales transformation.

FIG. 10B illustrates the dependence of energy on the distance between the surface of nanostructured storage material 22 and hydrogen molecule 16 near the location of a 5-7
20 defect. The binding energy $E_B(\text{C}, 5-7-7-5 \text{ defect})$ is about 0.14 eV, about 40 % bigger than $E_B(\text{C}, \text{planar})$, corresponding to an enhanced value of T_D of about 85K in this embodiment.

Nanostructures containing 5-7 pair defects can be prepared by various methods. Methods using mechanical deformations, for example, stretching, bending and twisting, have been described by B.I. Yakobson et al., in Physical Review Letters, vol. 76, p. 2511 (1996)).
25 Methods utilizing irradiation with electrons, neutrons, gamma rays and X rays have been described by V.H. Crespi et al. in Physical Review Letters, vol. 79, p. 2093 (1997). Additional methods, using mechanical deformations have been described by M. Cohen et al. in U.S. patent No. 5,993,697. Both publications and U.S. patent No. 5,993,697 are hereby incorporated in their entirety by reference.

Methods using variations of the chemical vapor deposition (CVD) have been described by X. B. Wang, Y. Q. Liu, and D. B. Zhu in Applied Physics A, vol. 71, p. 347 (2000), by X. B. Wang, Y. Q. Liu, and D. B. Zhu in Chemical Communications, No. 8, p. 751 (2001), by P. Nikolaev et al. in Chemical Physics Letters, vol. 313, p. 91 (1999), and by I. W. Chiang et al. in Journal Of Physical Chemistry B, vol. 105, p. 8297 (2001), all four publications
5 hereby incorporated in their entirety by this reference.

In some embodiments, variable amounts of cyclopentadiene, cycloheptatriene, and azulene are introduced, alone or in mixture, in the flow of the CVD process of any one of the referenced methods, in order to nucleate 5-7 pairs, or pentagon and heptagon defects
10 separately. These molecules can be introduced into the flow by boiling a precursor material in a first oven place upstream to the main oven, or by generating an aerosol of the precursor near the entrance of the main oven.

FIG. 11A illustrates some embodiments, where at least some the light elements 24 of nanostructured storage material 22 are charged, as indicated by the “-” signs on the atoms
15 of nanostructured storage material 22. Charging can be achieved by different methods. In some embodiments charges are introduced on nanostructured storage material 22 by forming an doping layer beneath or above nanostructured storage material 22 from dopant atoms 70. In the embodiment shown dopant atoms 70 donate electrons to light elements 24. In other embodiments dopant atoms 70 may accept electrons from light elements 24.
20 Accordingly, the introduced charges can be electrons or holes.

FIG. 11B illustrates the dependence of energy on the distance between the surface of charged nanostructured storage material 22 and hydrogen molecule 16. The binding energy $E_B(C, \text{charged})$ is about 0.15 eV, about 50 % bigger than $E_B(C, \text{planar})$, corresponding to an enhanced value of T_D of about 90K in this embodiment.

25 In some embodiments sp^2 bonds 8 can be modified by forming a magnetically ordered nanostructured storage material 22. These magnetic moments can order into an ordered magnetic state, which can also modify sp^2 bonds 8. Ordered magnetic states include ferromagnetic ordering, antiferromagnetic ordering and ferromagnetic ordering.

In some embodiments sp^2 bonds 8 can be modified by exposing nanostructured storage material 22 to a magnetic field.

Some embodiments combine two or more of the above-described embodiments. For example, some embodiments include localized defects, a curvature to nanostructured storage material 22, and 5-7 pairs. Some embodiments include vacancies and a donor layer. Some embodiments include one embodiment in one area of nanostructured storage material 22, and another embodiment in another area of nanostructured storage material 22. For example, during the growth of nanostructured storage material 22, a nanotube may grow in an area of an otherwise flat planar layer. All combinations of the above
10 embodiments are understood to be within the scope of the invention.

Although the various aspects of the present invention have been described with respect to certain embodiments, it is understood that the invention is entitled to protection within the full scope of the appended claims.

CLAIMS**We claim:**

1. A storage system, comprising:
a nanostructured storage material, comprising:
5 a network of a plurality of light elements, wherein the light elements are selected from the group consisting of Be, B, C, N, O, F, Mg, P, S, and Cl, wherein
the plurality of light elements are coupled by modified sp^2 bonds.
- 10 2. The storage system of claim 1, wherein
the binding energy of hydrogen to the nanostructured storage material with modified sp^2 bonds is greater than the binding energy of hydrogen to the nanostructured storage material with unmodified sp^2 bonds, wherein
hydrogen has a binding energy to the nanostructured storage
15 material.
3. The storage system of claim 2, wherein
the binding energy of hydrogen to the nanostructured storage material with modified sp^2 bonds is greater than about 0.10 eV.
4. The storage system of claim 1, wherein
20 the desorption temperature of hydrogen to the nanostructured storage material with modified sp^2 bonds is greater than the desorption temperature of hydrogen to the nanostructured storage material with unmodified sp^2 bonds, wherein
hydrogen has a desorption temperature to the nanostructured
25 storage material.
5. The storage system of claim 4, wherein
the desorption temperature of hydrogen to the nanostructured storage material is greater than about 60K.
6. The storage system of claim 4, wherein

the nanostructured storage material with modified sp^2 bonds is capable of adsorbing more hydrogen than the nanostructured storage material with unmodified sp^2 bonds in a range of temperatures around the desorption temperature of hydrogen, wherein

5 the nanostructured material is capable of adsorbing hydrogen.

7. The storage system of claim 1, wherein the nanostructured storage material has a chemical composition that modifies the Sp^2 bonds, wherein

the nanostructured storage material has a chemical composition.

10 8. The storage system of claim 7, wherein

the chemical composition of the nanostructured storage material is $B_xC_yN_z$, BN, BC_2N , C_3N_4 , MgB_2 , Be_3N_2 , BeB_2 , B_2O , B, BeO, $AlCl_3$, Al_4C_3 , AlF_3 , Al_2O_3 , Al_2S_3 , Mg_2Si , Mg_3N_2 , Li_3N , Li_2S , Na_2S , AlB_2 , or Na_2S_4 , and mixtures of the above, wherein x, y, and z are integers.

15 9. The storage system of claim 1, wherein

the nanostructured storage material has a non-planar shape that modifies the sp^2 bonds.

10. The storage system of claim 9, wherein the non-planar shape comprises: at least one of a thin nanoplatelet, a thick nanoplatelet, and an intercalated nanoplatelet.

20 11. The storage system of claim 10, wherein the at least one of a thin nanoplatelet, a thick nanoplatelet, and an intercalated nanoplatelet is in heterogeneous form.

12. The storage system of claim 9, wherein the non-planar shape comprises:

25 at least one of an empty nanocage, a filled nanocage, a multifaceted nanocage, an empty nanococoon, a filled nanococoon, a multifaceted nanococoon, a nanotorus, a nanocoil, a buckyball, and a nanohorn.

13. The storage system of claim 12, wherein the at least one of an empty nanocage, a filled nanocage, a multifaceted nanocage, an empty nanococoon, a filled

nanococoon, a multifaceted nanococoon, a nanotorus, a nanocoil, a buckyball, and a nanohorn is in a heterogeneous form.

14. The storage system of claim 9, wherein the non-planar shape comprises:
at least one of a single walled nanotube, a double walled nanotube, a multi
5 walled nanotube, a nanotube with zig-zag chirality, a nanotube with a mixture of
chiralities, a twisted nanotube, a straight nanotube, a bent nanotube, a kinked
nanotube, a curled nanotube, a flattened nanotube, a round nanotube, a
turbostratic nanofiber, a highly oriented nanofiber, a twisted nanofiber, a straight
nanofiber, a curled nanofiber, a rigid nanofiber, a nanorod, a nanowire, a rope of
10 nanotubes, a braid of nanotubes, and a bundle of nanotubes.

15. The storage system of claim 14, wherein the at least one of a single walled
nanotube, a double walled nanotube, a multi walled nanotube, a nanotube with zig-zag
chirality, a nanotube with a mixture of chiralities, a twisted nanotube, a straight nanotube,
a bent nanotube, a kinked nanotube, a curled nanotube, a flattened nanotube, a round
15 nanotube, a turbostratic nanofiber, a highly oriented nanofiber, a twisted nanofiber, a
straight nanofiber, a curled nanofiber, a rigid nanofiber, a nanorod, a nanowire, a rope of
nanotubes, a braid of nanotubes, and a bundle of nanotubes is in a heterogeneous form.

16. The storage system of claim 1, wherein
the nanostructured storage material comprises a plurality of defects that
20 modify the sp^2 bonds.

17. The storage system of claim 16, wherein
the plurality of defects comprise light elements of a first kind implanted
into a network of light elements of a second kind.

18. The storage system of claim 16, wherein
25 the plurality of defects comprise light elements of a first kind implanted
into a network of light elements of a second kind and a third kind.

19. The storage system of claim 16, wherein
the plurality of defects comprise a plurality of light elements removed
from the network of plurality of light elements.

30 20. The storage system of claim 19, wherein

the plurality of defects comprise a plurality of hydrogen atoms coupled to the network of the plurality of the light elements in place of the removed plurality of light elements.

21. The storage system of claim 16, wherein

5 the plurality of defects comprise a plurality of pentagons of the light elements, and a plurality of heptagons of the light elements.

22. The storage system of claim 21, wherein

pentagons of light elements and heptagons of light elements are neighbors, forming 5-7 pairs.

10 23. The storage system of claim 1, wherein

the nanostructured storage material further comprises a plurality of donor atoms, coupled to the nanostructured storage material to transfer charges onto the plurality of light elements that modify the sp^2 bonds.

24. The storage system of claim 1, wherein

15 the nanostructured storage material further comprises a plurality of acceptor atoms, coupled to the nanostructured storage material to transfer charges from the plurality of light elements that modify the sp^2 bonds.

25. A storage system, comprising:

a nanostructured storage means, comprising:

20 a network means of a plurality of light elements, wherein the light elements are selected from the group consisting of Be, B, C, N, O, F, Mg, P, S, and Cl, wherein

the plurality of light elements are coupled by modified sp^2 bonds.

26. A method of forming a storage system, the method comprising:

25 selecting a plurality of light elements from the group consisting of Be, B, C, N, O, F, Mg, P, S, and Cl; and

forming a nanostructured storage material, comprising:

forming a network of the selected plurality of light elements with modified sp^2 bonds.

27. The claim of 26, wherein forming the nanostructured storage material comprises:

forming the nanostructured storage material with modified sp^2 bonds capable of storing more hydrogen than the nanostructured storage material with unmodified sp^2 bonds, wherein the nanostructured material is capable of storing hydrogen.

28. The storage system of claim 26, wherein forming the nanostructured storage material comprises:

forming the nanostructured storage material with modified sp^2 bonds so that the binding energy of hydrogen to the nanostructured storage material with modified sp^2 bonds is greater than the binding energy of hydrogen to the nanostructured storage material with unmodified sp^2 bonds, wherein hydrogen has a binding energy to the nanostructured storage material.

29. The storage system of claim 26, wherein forming the nanostructured storage material comprises:

forming the nanostructured storage material with modified sp^2 bonds so that the desorption temperature of hydrogen to the nanostructured storage material with modified sp^2 bonds is greater than the desorption temperature of hydrogen to the nanostructured storage material with unmodified sp^2 bonds, wherein hydrogen has a desorption temperature to the nanostructured storage material.

30. The method of claim 26, wherein forming the nanostructured storage material comprises:

forming the nanostructured storage material with a chemical composition that modifies the sp^2 bonds, wherein the nanostructured storage material has a chemical composition.

31. The method of claim 30, wherein forming the nanostructured storage material comprises:

including doping gases into the flow of the chemical vapor deposition synthesis, wherein

the nanostructured storage material is formed by a chemical vapor deposition synthesis.

5 32. The method of claim 31, wherein including doping gases into the flow comprises:

including a doping gas, selected from the group consisting of NH_3 , CH_3NH_2 , $(\text{CH}_3)_2\text{NH}$, $(\text{CH}_3)_3\text{N}$, BCl_3 , BF_3 , B_2H_6 , a borohydride, SiH_4 , Si_2H_6 , SiCl_4 , SiF_4 , SiH_2Cl_2 , H_2S , and PH_3 .

10 33. The method of claim 30, wherein forming the nanostructured storage material comprises:

forming a powder mixture by introducing traces of selected elements into a graphite powder;

15 hot-pressing the powder mixture into a form, suitable for use as an electrode; and

using the hot-pressed powder as an electrode in an arc synthesis of nanostructured storage material.

34. The method of claim 30, wherein forming the nanostructured storage material comprises:

20 ball-milling the nanostructured storage material with a powder of a selected element.

35. The method of claim 26, wherein forming the nanostructured storage material comprises:

25 forming the nanostructured storage material with a non-planar shape that modifies the sp^2 bonds.

36. The method of claim 26, wherein forming the nanostructured storage material comprises:

forming the nanostructured storage material with a plurality of defects that modify the sp^2 bonds.

37. The method of claim 36, wherein forming the nanostructured storage material comprises:

5 exposing the nanostructured storage material to a flow of ozone; and
annealing the nanostructured storage material in a temperature range
between about 400°C and about 1800°C.

38. The method of claim 37, wherein the annealing comprises:
annealing in one of a vacuum, a neutral atmosphere and a hydrogen
containing atmosphere.

39. The method of claim 36, wherein forming the nanostructured storage
10 material comprises:

removing light elements from the nanostructured storage material by a
method, selected from the group of irradiation with electrons, neutrons, ions,
gamma rays, X-rays, and microwaves.

40. The method of claim 36, wherein forming the nanostructured storage
15 material comprises:

nucleating 5-7 pair defects by introducing at least one of cyclopentadiene,
cycloheptatriene, and azulene, into the flow of the chemical vapor deposition
synthesis, wherein

20 the nanostructured storage material is formed by a chemical vapor
deposition synthesis.

41. The method of claim 26, wherein forming the nanostructured storage
material comprises:

forming the nanostructured storage material with a charge transfer layer
that modifies the sp^2 bonds, wherein

25 the charge transfer layer is capable of transferring electrons to or
from the nanostructured material.

42. A method of storing hydrogen in a storage system, the method comprising:
providing a nanostructured storage material, comprising:

a network of a plurality of light elements, wherein the light elements are selected from the group consisting of Be, B, C, N, O, F, Mg, P, S, and Cl, wherein

5 the plurality of light elements are coupled by modified sp^2
 bonds; and
storing hydrogen in the nanostructured storage material.
